INTRODUCTION

1. PURPOSE OF THE INVESTIGATION

The *Mount Wilson Catalogue* had its origin in a request by Professor Kapteyn, shortly after the completion of the 60-inch telescope, for assistance in determining the brightness of stars in the Selected Areas. The need was chiefly for magnitudes of faint stars to serve as the basis for a study of stellar distribution to the lowest practicable limit of brightness. The magnitudes were to be photographic, on the scale of Pogson, referred to the international zero point. The fields to be observed were the 139 Areas on and north of declination −15°.

The first step in the undertaking was to photograph each Area with the 60-inch reflector, with an exposure of one hour on a Lumière Σ plate. These photographs, referred to below as the "long-exposure" plates, were made by Messrs. Babcock and Fath during the years 1909-1912. Except for a few fields, the 60-minute exposure was followed by one of 3 minutes to aid in extending the scale to the faintest stars. Upon completion of the photographs, positive copies with an enlargement of one-third were made from the original negatives for use at Mount Wilson, while the originals were sent to the Astronomical Laboratory at Groningen for measurement and reduction. About a dozen of these photographs were subsequently repeated by Seares, usually because of unsatisfactory atmospheric conditions at the time the originals were made.

The second step was that of providing suitable standards of magnitude in each of the 139 Areas for the reduction of the long-exposure photographs. This, however, developed into two separate investigations of large extent, the first relating to the magnitude scale of the Polar Sequence, the second, to the determination of the standards themselves.

At the time observations were begun, the methods of photographic photometry were little developed and their reliability was unknown. Much experimental work had been done at the Harvard Observatory, and accordant provisional results for the magnitudes of the Polar Sequence had been published in *Harvard Circular*, No. 170, but none of the methods had been tried with a large reflector. A preliminary investigation with the 60-inch telescope was accordingly begun in 1910 to determine the best method of establishing the scale over a long interval of brightness. It was found that wire-gauze screens and circular or annular diaphragms of various sizes, used in combination with the full aperture, gave nearly the same result, whence it was inferred that differences in the diffraction pattern, which might well affect measures made with diaphragms, could be neglected. For ease of comparison with the Harvard magnitudes of the Polar Sequence, all the early Mount Wilson measures were made on stars near the Pole. These measures soon brought to light a divergence between the Harvard and Mount Wilson scales, amounting to 7 per cent for stars brighter than the eleventh magnitude and to even more for those fainter than the sixteenth magnitude. Between these two magnitudes, however, the scales were found to be parallel, with a zero-point difference of 0.40 mag.[1] This necessitated a careful investigation of the whole question and an independent determination of the scale of the Polar Sequence. The results, which include both photographic and photovisual magnitudes, fully confirm the provisional measures.[1]

Mt. Wilson Communications, No. 8; *Proceedings of the National Academy of Sciences*, 1, 309, 1915.

In the meantime, a revision and extension of the Harvard measures in *Harvard Circular*, No. 170 had led to the results published in *Harvard Annals*, **71**. With the aid of the observational details given in that volume and the color indices of the individual stars derived from the Mount Wilson photographic and photovisual magnitudes, it was possible to reduce the Harvard magnitudes to the color system of the reflector. The remaining scale difference was then found to be

$$MW - H = + 0.061 \, (H - 6)$$

for $H < 10$, and a constant, + 0.24 mag., for $H = 10$ to 16.

Lack of independent confirmation of these results led Seares and M. Humason in 1922 to re-examine the photographic and photovisual scales in the critical region of the bright stars.[2] The 10-inch Cooke refractor, which had not been used in the earlier investigations, and a wire-gauze screen were employed. The reduction constant of the screen used for these observations (3.02 mags.) was carefully determined from measures of Polar Sequence stars between the tenth and sixteenth magnitudes, where the slope of the scale was not in question. No appreciable systematic deviation from the earlier results was found. All the measures were then combined into mean values which represent the finally adopted Mount Wilson magnitudes for the Polar Sequence.[3] Confirmatory evidence was obtained by other observers about the same time, notably at Harvard and at Greenwich; and in 1922 the Commission on Stellar Photometry proposed a scale, based on all the data then available, which was adopted by the International Astronomical Union at the meeting at Rome in the same year. Aside from small accidental differences affecting the magnitudes of individual stars, the international scale is sensibly identical with that determined at Mount Wilson.

These circumstances are of interest, not because the scale of the Polar Sequence is it any sense the basis of the scale of the present *Catalogue*—in fact, the magnitudes of stars an the Pole have been used only to determine the zero point for the different Areas—but because the methods used to establish the scale of the *Catalogue* were the same as those successfully applied in the case of the polar stars. That a similar success has probably been attained in the *Catalogue* is indicated by the comparison of results given in sections 11 and 12.

A matter that had also to be investigated with care was the correction for distance from the optical axis which must be applied to measures of stars photographed with the 60-inch reflector. Since this correction depends on the focal ratio, it had to be determined for each of the apertures used. For the diaphragms its values are small, and in some cases negligible within the limits of the adopted field; but for the full aperture (ratio 1 to 5) the correction is large and varies rapidly with the distance. Further, the correction also depends on the size of the image and hence, unless accurately determined, becomes a source of systematic error affecting the magnitudes.

The relationship between the various contributing factors is still further complicated by the fact that the correction is seriously modified, especially for the full aperture, by deformations of the large mirror which result from any sudden change in temperature. When these changes occur, the disturbances are very troublesome and greatly increase the labor of deriving normal values of the correction. In order to provide an abundance of images for measurement, special photographs of rich fields were used to obtain provisional results; but the revision which led to the adopted values became an integral part of the investigation of the Polar Sequence.

2. PHOTOGRAPHS FOR MAGNITUDE SCALE

In the meantime, a program for the determination of standard magnitudes in the Selected Areas had been arranged and observations were in progress. The exposure time for the photographs to be used in deriving the magnitude scale was determined by the fact that the scale fixed by a group of standards can be extended downward with satisfactory accuracy about one magnitude by means of a long exposure on a single plate. Since the long-exposure photographs had been exposed 60 minutes, a maximum of 15 minutes was accordingly adopted for deriving the standards themselves. Since polar comparisons of this length are troublesome, it seemed best not to attempt to transfer the scale of the Polar Sequence to the individual Areas, but instead to establish the scale in each Area independently, by comparing exposures of the same length made with full and reduced apertures, and to refer the results to the international zero point by means of zone and polar comparisons of short exposure.

In order that the standards might cover a wide interval in brightness, photographs of 2 minutes exposure were also included in the program of diaphragm plates; and further diversification was obtained by using diaphragms differing considerably in size and character in making the reduced-aperture exposures. With rare exceptions, the images of the brightest stars in the field were thus brought within the limits of measurable size. This arrangement also had the advantage that residual effects on the scale arising from differences in diffraction pattern and from uncertainties in the distance correction were much reduced.

As a general precaution, the exposures on each plate were made in a symmetrical order. This doubles the number of images for measurement, greatly reduces the errors arising from changes in gradation and in atmospheric conditions, and practically obviates the danger of mistaking a defect in the film for the image of a star whose brightness is near the limiting magnitude.

The program of exposures finally adopted for the determination of the scale in each Area was as follows:

Exposure	Apertures	No. Plates
15^m	60, *S*, *S*, 60	1
15	60, 32, 32, 60	1
2	60, 32, 14, 9, 9, 14, 32, 60	2

Under "Apertures," *S* indicates a 60-inch wire-gauze screen, while the numbers are the diameters of the various apertures, expressed in inches. The photographs for each Area were taken on at least two different nights, a plate of 15 minutes exposure and one of 2 minutes usually being made on the same night.

The photographs were taken with a plate-holder base provided with an additional slide, controlled by a screw with a graduated head. The plate-holder could thus be shifted between exposures without disturbing the adjustment of the guiding microscope.

In photometric observations with the 60-inch reflector the Newtonian flat and its cell are blocked out by an opaque circular screen, 23 inches in diameter, mounted centrally over the end of the tube. The "full" aperture of 60 inches and the 32-inch diaphragm are thus annular openings. In order to clear the central screen, the 14- and 9-inch diaphragms were necessarily placed in an eccentric position over the end of the tube. These diaphragms were always shifted in position between the two exposures on any plate, by rotation about the optical axis.

The reduction constants [1] for the various apertures are:

Aperture	*S*	32	14	9
Reduction Constant	3.06	1.96	2.97	3.93

3. PHOTOGRAPHS FOR ZERO POINT

The relative magnitudes derived for each Area by combining the full- and reduced-aperture exposures were referred to the international zero point by means of zone and polar comparisons. Each Area was connected with each of the adjacent Areas of the same zone by two photographs of multiple exposure. For any pair of adjacent Areas, the arrangement of the exposures, which were always 2 minutes with the full aperture, was, First plate: A_1, A_2, A_2, A_1; Second plate: A_2, A_1, A_1, A_2.

Each zone, except that at declination $-15°$, was connected directly with the Pole at six points, separated by approximately four hours in right ascension. The zone at $-15°$ was similarly connected with the zone at 0°. Three polar comparisons were made for each of the six points in the 0° zone, and two for all of the other zones. These exposures, which were also 2 minutes with the full aperture, were usually arranged in the order, A, Pole, Pole, A, although the initial and final exposures were sometimes on the Pole. In so far as possible, the intercomparison exposures were made when the two fields compared were at equal altitudes; but the exigencies of a complicated program of observing did not always admit close compliance with this condition.

The subsequent identification of stars on the comparison plates was greatly facilitated by shifting the plate between exposures in the direction of right ascension for one field, and of declination for the other. The orientation of any pair of images thus indicates the field to which the star belongs.

4. RECORD OF PLATES

The numbers of photographs required for the various parts of the program, exclusive of repeated plates, were:

Long-exposure plates	139
Diaphragm plates	556
Zone comparisons	288
Polar comparisons	80
Total	1063

---

NOTES TO TABLE I

Plate Numbers:—Plates 42-535b belong to the SA series and are long-exposure photographs; all others are of series P and are either diaphragm or comparison photographs, or, in a few cases, long-exposure photographs, repeated because of defects in the original plates. Rejected photographs are not listed.

Field:—The fields observed are designated by the Area number, or in case of exposures on the Pole by the letter P. A double entry in the field column indicates a comparison photograph.

Seeing:—The observations were begun before the scale of seeing now in use had been adopted. For plates 104-535b the scale is 0-5; for the others, excepting the first 10, it is 1-10, the index number increasing with the quality.

Observers:—The first 16 plates are by Babcock; Nos. 193-535b by Fath. The following, 232 plates in all, were taken by Shapley:

2066–2114
2222–2334
2355–2373
2453–2458
2493–2523
2563–2654
2704–2765
2820–2888
2967–2984
3025–3029
3208–3243
3409–3510
3655–3723
3770–3772
3839–3845
3953–3999
4077–4078
4271–4355
4392–4406
4512–4539
4718
4750–4774
5096

The remaining 712 plates are by Seares.

For convenience, the designation "diaphragm plates" is used to denote all photographs involving exposures with reduced aperture, whether the reduction was made with the aid of the diaphragms or by means of the wire-gauze screen.

The long-exposure photographs by Babcock and Fath were finished in 1912. The observations for the diaphragm and comparison photographs were begun in January, 1913, and practically completed in November, 1919. For these the observers were Seares and Shapley. The plates used were partly Seed 27's and partly Seed 30's. All photographs were centered on the central star of the respective Areas.

The several settings of the telescope on each Area required to complete the program were facilitated by charts made from the positive enlargements of the long-exposure plates. These charts also played a useful part in the measurement and reduction of the photographs.

A journal of observations is given in Table I, and the grouping of the scale plates for each Area is shown in Table II. Thus for Area 1 the long-exposure photograph is plate 487; Nos. 1102 and 1121 include 15-minute exposures with the $60-32$ and $60-S$ combinations of apertures, while 1103 and 1122 are the short-exposure diaphragm photographs. The grouping for the zone- and polar-comparison plates is given in Tables VII and VIII (pp. XXIX, XXX). The dates of observation for any Area may be found by reference to Table I.

These tables do not include plates rejected before measurement, but only those used in the preparation of the *Catalogue*. In a few instances the reduction of an accepted plate gave discordant results for the magnitude scale. An additional plate was then exposed, measured, and reduced, the results being combined with the normal complement of exposures. The additional plates are listed in the notes following Tables II, VII, and VIII.

5. MEASUREMENT AND REDUCTION OF PLATES

a. Long-Exposure Photographs.—Most of these photographs, which were measured and reduced at Groningen, include an exposure of 3 minutes in addition to the primary exposure of 60 minutes. The fields measured were $15' \times 15'$ for galactic latitudes less than 40°, and $20' \times 20'$ for higher latitudes. The centers are nearly coincident with the central star of the respective Areas, the exact location being defined in section 8a, page XXXVII. In that section it is further explained that the diameters of all the images were estimated in seconds of arc by means of an ocular scale in the observing microscope of the Repsold measuring machine of the Kapteyn Laboratory. The diameter of the faintest stars on the

85 3745; 60, 3^m and 30^m.

plate is by no means zero; in fact, from a certain limit of brightness down, the diameter ceases to diminish. For these stars the scale of diameters was prolonged by an estimate of the density of the image, the faintest star on the plate being called −0, while the upward steps were consecutively 0, +0, −1, 1, +1, etc.

To transform these estimates into magnitudes, the results for selected standards, which had been determined at Mount Wilson and forwarded to Groningen (see page XXI), were plotted against the diameters for both the 60-minute and the 3-minute exposures after correction for distance from the center of the plate. The distance correction used was that derived at Mount Wilson, expressed in units of a certain scale (section 5b, page XIX). These scale units were converted into diameters of the Groningen scale by means of plates for which both the diameters of the images and the corresponding readings of the Mount Wilson scale were known. Since the photographs measured at Groningen were exposed longer than the diaphragm plates, standards for the faintest stars were generally not available. To obtain these the curve connecting diameter and magnitude was prolonged by means of the short-exposure images as follows: For Area 4, for instance, the magnitudes corresponding to diameters 5.0, 4.0, ... are those given in Table III. The curve defined by the long-exposure images could be read down to diameter 1.0; that from the short-exposure images, to diameter −0.3, which corresponds to the faintest stars measured. The differences between the magnitudes read from the two curves for the same value of the diameter are thus determined to diameter 1.0. Their values increase with decreasing diameter, and by extrapolation we find 2.68 for diameter 0.0 and 2.70 for diameter −0.3. The addition of these differences to the corresponding magnitudes from the short-exposure curve, which is defined throughout by the standards, gives for the long-exposure curve, for diameter 0.0, magnitude 17.92, and for diameter −0.3, magnitude 18.04. These values provide for the extension of the long-exposure curve to the faintest stars.

TABLE III

Extension of Scale

Diameter	Magnitude		Difference
	60-Min. Exp.	3-Min. Exp.	
+5.0	15.82	13.36	+2.46
4.0	16.16	13.76	+2.40
3.0	16.57	14.15	+2.42
2.0	17.02	14.51	+2.51
+1.0	17.47	14.87	+2.60
0.0	(17.92)	15.24	(+2.68)
−0.3	(18.04)	15.34	(+2.70)

The other Areas have been treated similarly. In a few cases the short exposure is missing; the curve connecting diameter and magnitude was then simply prolonged as far as diameter −0.3.

The magnitudes of all the stars on the plate corresponding to the estimated diameters were derived from these curves. For the faintest stars only the long-exposure image is visible; for brighter stars the short-exposure image also appears, and the two values of the magnitude then available have been combined with the weights shown in Table IV.

b. Diaphragm Photographs.—Kapteyn's request for standard magnitudes contemplated the observation of only a small number of stars, 25 or 30 in each field. It was soon found, however, that the sensitiveness of the distance correction to slight changes in the figure of the mirror leads to considerable uncertainty in the magnitude scale when the number of stars discussed is small. Since the results of the investigation could be greatly strengthened by observing more stars, it was finally decided to derive magnitudes for all objects appearing on the diaphragm photographs. This meant a great increase in labor, but the gain in precision and in the number of stars having well-determined magnitudes has justified the decision.

In general the measures and reductions made at Mount Wilson are in accordance with the methods described in *Mt. Wilson Contr.*, No. 80,[1] which may be consulted for details not explained here. The field measured was circular, 23′ in diameter and centered on the bright central star of the Area. The negative was mounted on the movable stage of a low-power compound microscope magnifying about 5 diameters. The images on the negative were compared with a scale of star images, placed at the common focus of the eye-piece and objective of the microscope.

TABLE IV

Weights for Long-Exposure Magnitudes

Diameter		Relative Weights	
3-Min. Exp.	60-Min. Exp.	3-Min. Exp.	60-Min. Exp.
<2.5	.....	1	1
>2.5	<8.0	1	½
>2.5	>8.0	1	0

The scales used were prepared in the usual manner by exposing a photographic plate successively to the same star for time intervals increasing in geometrical progression with the factor 4/3. For the bright end of the scale the interval between successive images averages about 0.3 mag., but for images near the limiting magnitude the scale interval is somewhat larger. Besides this progressive change in the interval, both of the scales used show irregular variations. For the primary scale (No. III) these were well determined during the investigation of the Polar Sequence. Comparison of measures of the same photograph made with the two scales then gave the corrections for irregularity in the second scale (No. V). These were combined with the corrections for distance error and tabulated with scale reading and distance as arguments, in such a form as to give directly the corrected scale reading.

Since the correction tables refer to individual scales, they are of no general interest, and hence are not printed. It may be remarked, however, that the correction for the faintest images at the edge of the useful field for the full aperture corresponds to an average of

---

[1] *Astrophysical Journal*, **39**, 307, 1914.

-0.5 or -0.6 mag. The brightest images, on the other hand, require a positive correction of about the same amount. The limiting magnitude thus shows a large variation with distance from the optical axis, and near this limit the *Catalogue* is far from complete.[1]

During measurement the identification of stars was made with the aid of the charts printed from the positive enlargements of the long-exposure photographs. Five circles concentric with the central star were drawn on the charts, the outermost coinciding with the boundary of the 23′ field, the others dividing the radius of the field into five equal parts, corresponding to five units of distance. The field was further subdivided into 45° sectors. All the stars visible on the chart were then numbered consecutively, in a systematic manner. The numbers thus assigned were retained until the results were finally combined with the Groningen measures of the long-exposure photographs and assembled in catalogue form. With the configuration of stars in each section of the numbered chart as a guide, it was scarcely possible to overlook a star in measuring the plates.

All the images of a star on any given plate were measured successively, a single estimate, to the nearest tenth of a scale interval, being made for each image. After duplicate measurement by a second observer, mean scale readings were formed for the four comparable estimates corresponding to each aperture, that is, for estimates by two observers on each of the two images with full aperture, 32-inch diaphragm, etc. The mean readings and the distance from the optical axis, which was read directly from the chart with the aid of the concentric circles, were then used to interpolate from the correction tables the corrected scale readings, s and s_1, referring, respectively, to the full and reduced apertures.

The difference for any star, $\Delta s = s_1 - s$, corresponds to the reduction constant Δm for the particular aperture used. Were the values of Δs for different stars always the same, the transformation of scale readings into relative magnitudes would have been very simple. In general, however, Δs shows dependence on s, in addition to the accidental fluctuations normally to be expected. The accidental irregularities were minimized by plotting the values of Δs for all the stars on the plate bright enough to produce a secondary image against the corresponding values of the scale reading s. A smooth curve through the plotted points then gave the values of Δs adopted for the transformation into magnitudes.

This transformation was made by the method of Schwarzschild.[2] The results were collected in tables which give values of m and m_1, corresponding to the primary and secondary exposures, respectively, with the corrected scale reading as argument. The zero point for m and m_1 in any Area was always the same, but otherwise, quite arbitrary. From these tables magnitudes corresponding to the scale readings s and s_1 were then interpolated for all the stars measured.

For the brightest stars the primary images cannot be measured; for the faintest stars there is but one value of the magnitude, because the secondary image is lacking. For stars of intermediate brightness, showing measurable images for both full and reduced apertures, the mean of the two corresponding magnitudes was adopted as the result from that particular combination of apertures.

---

[1] See *Mt. Wilson Contr.*, No. 301; *Astrophysical Journal*, 62, 320, 1921, Tables Ia, Ib.

[2] *Astronomische Nachrichten*, 172, 65, 1906. For an illustrative example, see *Mt. Wilson Contr.*, No. 80, Table V; *Astrophysical Journal*, 39, 307, 1914.

The series of relative magnitudes thus found represents a "scale determination" for the field in question. In case secondary exposures with additional diaphragms were available, other determinations could also be made from the same plate, the primary images being used in succession with those obtained with the different diaphragms. For the adopted program of exposures (see page IX) the useful combinations of apertures for scale determinations are

Exposure time	15^m	15^m	2^m
No. of Plates	1	1	2
Combinations	60−32	60−*S*	60−32, 60−14, 60−9

The four diaphragm plates for each Area therefore yield eight determinations of the scale and a possible maximum of 16 values of the magnitude of any star. In general, however, the 60−9 combination does not give satisfactory determinations of the scale. The reduction constant of nearly four magnitudes is so large that only a few stars are represented by both primary and secondary images. The resulting curve for Δs is short and the transformation of scale readings into magnitudes uncertain. Magnitudes corresponding to images recorded with the 9-inch diaphragm were therefore usually obtained with the aid of the scales derived from the 60−32 and 60−14 combinations for the same plate. This was done by entering the *m*-column of the magnitude table with the scale reading for the 9-aperture as argument and subtracting from the interpolated magnitude the reduction constant of 3.93 mag.

This reduces the number of scale determinations to six per Area. The maximum number of values of the brightness of any star as found from the four diaphragm plates remains 16 as before; but the number of cases in which 16 values were actually obtained is relatively small. Bright stars were measurable only when the exposure was short or the aperture was reduced, while very faint stars were recorded only with the full-aperture exposures of 15 minutes. For the faintest stars, therefore, the diaphragm plates give but two values of the magnitude, and sometimes only one, because of differences in limiting magnitude for the two 15-minute plates.

The magnitudes resulting from the six scale determinations for each Area were all reduced to the provisional zero point for the 60−32 combination on the plate of 15 minutes exposure. Mean relative magnitudes were then formed for each star. Individual values giving residuals greater than 0.4 mag. were rejected.

For fields in high galactic latitudes, the constants for reduction to the common zero point were based on magnitude differences for all the stars measured. In richer fields they were derived from a selected group of a hundred or more stars, well distributed over the field and covering the whole range of brightness.

As far as the data afforded by the diaphragm plates are concerned, the mean relative magnitudes are the final result. After reduction to the international zero point, selected standards—from 25 to 100 for each Area—were forwarded to Groningen for use in reducing the measures of the long-exposure photographs as described in section 5a. The magnitudes derived from these photographs and the coordinates of the stars (see section 8a), arranged in catalogue form, were then sent to Pasadena for combination with the measures of the diaphragm plates, which were thus strengthened and extended to fainter stars. The procedure followed in combining the two series of magnitudes is explained in section 9. The zero-point reduction is, however, first to be considered, for the zero points of the mean relative magnitudes for each Area are arbitrary. To reduce these results to a homogeneous system is the purpose of the zone- and polar-comparison photographs.

c. Zone and Polar Comparisons.—The comparison photographs were measured in the same manner as the diaphragm plates. The result is a mean scale reading for each star, based on single measures by two observers of each of the two images and corrected, as usual, for distance error and scale irregularity. For any star in a field F_1 the magnitude m_1 corresponds to the scale reading s_1. For any star in a second field F_2, which is to be reduced to the zero point of F_1, the reading and relative magnitude are s_2 and m_2. The zero-point differences given by any comparison photograph connecting F_1 and F_2 were found by plotting values of m_1 against s_1, and reading from the resulting curve the magnitudes m_2' corresponding to scale reading s_2 for all the stars in the field F_2. The mean of the differences $m_2' - m_2$, corrected for atmospheric extinction, is the required zero-point difference. Each of the 368 comparison photographs was treated in this manner. The mean observed differences for the pairs of fields thus connected, which are the data upon which the zero-point reduction is based, are given under the headings Δ and δ in Tables VII and VIII, respectively.

6. ZERO-POINT REDUCTION

a. Theoretical Relations.—Much attention has been given to the reduction of the relative magnitudes to a system homogeneous in respect to zero point, a matter that merits detailed explanation and some indication of the internal consistency of the results.

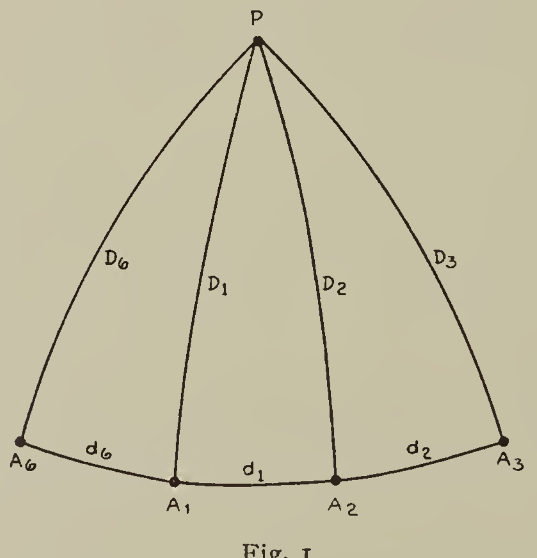

Fig. 1

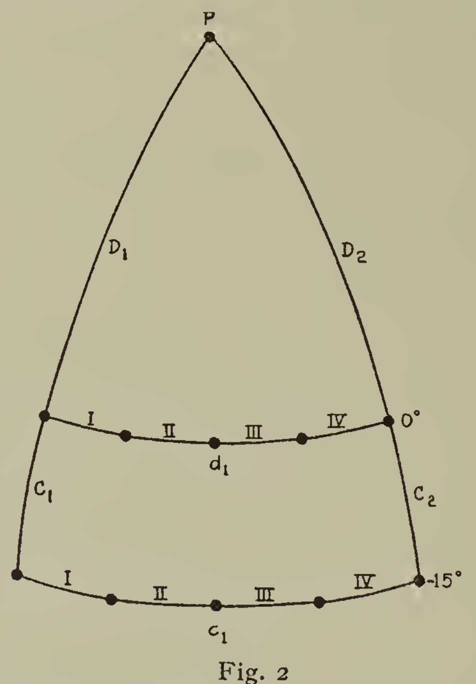

Fig. 2

The zero-point differences derived from the zone- and polar-comparison photographs as described in the preceding section may be grouped in series of closed circuits, each of which is subject to a closing condition, as in a triangulation net. The arrangement of the circuits, which in general are triangular with the Pole at one of the vertices, is illustrated in Figures 1 and 2. For the zone at $\delta = +75°$ each circuit includes three steps (Fig. 1); at +60° an intermediate Area appears between those connected with the Pole, while in all other zones (Fig. 2) there are three intermediate Areas. Since each polar comparison is common to two adjacent circuits, the six circuits of each zone must be discussed together. Further, since the zone at $\delta = -15°$ was connected with that at 0°, and not directly with the Pole, the circuits are as indicated in Figure 2—a triangle and a quadrilateral with one side in common—and the two zones must be reduced as a unit. The number of steps in each circuit and in the zones, which must also close, is therefore as shown in Table V. The grouping of this table indicates the four cases to be considered in deriving the adjustment formulæ. The case for + 75° is the simplest.

TABLE V

Number of Steps

Dec.	In Circuit	In Zone
+75°	3	6
60	4	12
45, 30, 15	6	24
{ 0	6	24 }
{ −15	10	24 }

Declination + 75°.—The adjusted zero-point differences in the triangle A_1PA_2, Figure 1, taken in the order $P-A_1$, $P-A_2$, A_1-A_2, are denoted by D_1, D_2, and d_1, respectively; the corresponding observed differences are Δ_1, Δ_2, and δ_1, and the respective adjustment corrections, V_1, V_2, and v_1.

In general the adjusted differences satisfy the linear closing conditions

$$\psi_n = D_n - D_{n+1} + d_n = 0 \tag{1}$$

while the observed differences give the closing error ϕ:

$$\Delta_n - \Delta_{n+1} + \delta_n = \phi_n \tag{2}$$

Once for all, it may be remarked that n has the values 1, 2, . . . 6. If, however, any subscript, s, exceeds 6, it is to be replaced by $s-6$; the only exception is in equations (9) and (36), where the subscript has its indicated value, since cyclic changes in notation are not involved in these formulæ.

The summation of (1) and (2) gives, respectively, the superfluous condition

$$\Sigma d = 0 \tag{3}$$

and the closing error of the zone

$$\Sigma\delta = \Sigma\phi = \epsilon \tag{4}$$

The problem is to determine adjustment corrections V_n and v_n such that

$$D_n = \Delta_n + V_n, \qquad d_n = \delta_n + v_n \tag{5}$$

satisfy (1). The general solution is[1]

$$V_n = P_D^2\left(\frac{\partial\psi_{n-1}}{\partial D_n}k_{n-1} + \frac{\partial\psi_n}{\partial D_n}k_n\right); \qquad v_n = P_d^2\frac{\partial\psi_n}{\partial d_n}k_n \tag{6}$$

---

[1] See, for example, Comstock, *Method of Least Squares* (Boston, 1890), p. 38. For a more complete discussion, Helmert, *Ausgleichungsrechnung* (Berlin, Teubner, 1907), p. 228, may be consulted.

in which ψ is the closing condition (1). Further,

$$P_D^2 = \frac{1}{[p_\Delta]}, \qquad P_d^2 = \frac{1}{[p_\delta]} \tag{7}$$

where p_Δ and p_δ are the weights of Δ and δ.

The quantities k are the correlates corresponding to the six conditions (1) and are defined by

$$\left.\begin{array}{l} [\alpha\alpha]\,k_1 + [\alpha\beta]\,k_2 + \cdots\cdots + [\alpha n]\,k_6 + \phi_1 = 0 \\ [\alpha\beta]\,k_1 + [\beta\beta]\,k_2 + \cdots\cdots + [\beta n]\,k_6 + \phi_2 = 0 \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \end{array}\right\} \tag{8}$$

in which

$$\left.\begin{array}{ll} \alpha_n = P_D \dfrac{\partial\psi_1}{\partial D_n}, & \alpha_{6+n} = P_d \dfrac{\partial\psi_1}{\partial d_n} \\ \beta_n = P_D \dfrac{\partial\psi_2}{\partial D_n}, & \beta_{6+n} = P_d \dfrac{\partial\psi_2}{\partial d_n} \\ \cdots\cdots\cdots, & \cdots\cdots\cdots\cdots \end{array}\right\} \tag{9}$$

For the present case the number of observation equations for Δ and δ is the same. Further, the individual comparisons are of equal weight. Hence we may write

$$P_D^2 = P_d^2 = 1$$

TABLE VI

Values of $\dfrac{\partial\psi_n}{\partial x}$

x	ψ_1	ψ_2	ψ_3	ψ_4	ψ_5	ψ_6
D_1	+1	0	0	0	0	−1
D_2	−1	+1	0	0	0	0
D_3	0	−1	+1	0	0	0
D_4	0	0	−1	+1	0	0
D_5	0	0	0	−1	+1	0
D_6	0	0	0	0	−1	+1
d_1	+1	0	0	0	0	0
d_2	0	+1	0	0	0	0
d_3	0	0	+1	0	0	0
d_4	0	0	0	+1	0	0
d_5	0	0	0	0	+1	0
d_6	0	0	0	0	0	+1
	α	β	γ	δ	ϵ	η

The values of α, β, etc., are therefore equal, respectively, to the differential coefficients appearing in (9). These derivatives are listed in Table VI. Combined according to (8), they give the correlate equations (10):

$$\left.\begin{array}{rrrrrrl} +3k_1 & -k_2 & & & & -k_6 & +\phi_1 = 0 \\ -k_1 & +3k_2 & -k_3 & & & & +\phi_2 = 0 \\ & -k_2 & +3k_3 & -k_4 & & & +\phi_3 = 0 \\ & & -k_3 & +3k_4 & -k_5 & & +\phi_4 = 0 \\ & & & -k_4 & +3k_5 & -k_6 & +\phi_5 = 0 \\ -k_1 & & & & -k_5 & +3k_6 & +\phi_6 = 0 \end{array}\right\} \tag{10}$$

which have the solution

$$-40\,k_n = 18\,\phi_n + 7\,\phi_{n+1} + 3\,\phi_{n+2} + 2\,\phi_{n+3} + \phi_{n+4} + 7\,\phi_{n+5} \tag{11}$$

The adjustment corrections (6) reduce to the simple form

$$V_n = k_n - k_{n-1}, \qquad v_n = k_n \tag{12}$$

and are controlled by the check equations

$$\Sigma\, V = 0, \qquad \Sigma\, v = -\,\Sigma\, \phi = -\,\epsilon \tag{13}$$

Finally, the adjusted zero-point differences are given by (5), which are themselves subject to the check equations

$$\Sigma\, D = \Sigma\, \Delta, \qquad \Sigma\, d = 0 \tag{14}$$

and, most important of all, equation (1). Formulæ (2), (11), (12), and (5) give the complete solution for the zone at $\delta = +75°$.

Declination $+60°$.—Because of the intermediate Area, the zero-point difference d_n in the preceding formulæ is to be replaced by two differences such that

$$d_n = d_n^{I} + d_n^{II} \tag{15}$$

where the weights of d_n^{I} and d_n^{II} are, respectively, equal to those of D_n. The closing conditions are

$$\psi_n = D_n - D_{n+1} + d_n^{I} + d_n^{II} = 0 \tag{16}$$

and the closing errors

$$\Delta_n - \Delta_{n+1} + \delta_n^{I} + \delta_n^{II} = \phi_n \tag{17}$$

The only effect on the preceding solution is the addition of six values for each of the coefficients listed in (9), namely α_{12+n}, β_{12+n}, etc. The additional derivatives are the same as those in the last six lines of Table VI, which are thus to be repeated. The correlate equations are the same as (10) with the coefficient 3 replaced by 4 throughout. Their solution is

$$-90\,k_n = 26\,\phi_n + 7\,\phi_{n+1} + 2\,\phi_{n+2} + \phi_{n+3} + 2\,\phi_{n+4} + 7\,\phi_{n+5} \tag{18}$$

The adjustment corrections and their checks are

$$\left.\begin{array}{l} V_n = k_n - k_{n-1}, \quad v_n^{I} = v_n^{II} = k_n \\ \Sigma\, V = 0, \quad \Sigma\, v^{I} + \Sigma\, v^{II} = -\,\Sigma\,\phi = -\,\epsilon \end{array}\right\} \tag{19}$$

Finally, the adjusted differences are given by

$$D_n = \Delta_n + V_n, \qquad d_n^{I} = \delta_n^{I} + k_n, \qquad d_n^{II} = \delta_n^{II} + k_n \tag{20}$$

with (14) and (16) as final check equations.

Since by (19) the adjustment corrections for the differences δ_n^{I} and δ_n^{II} are equal, an alternative method is available which is considerably simpler, especially for the cases still to be considered. It consists in using the original condition (1), instead of (16). This procedure gives, not v_n^{I} and v_n^{II}, but the total correction v_n for δ_n, which is then to be divided equally between the differences δ_n^{I} and δ_n^{II}.

The differential coefficients are the same as those given in Table VI, but it is now to be noted that P_d^2 is no longer unity but has the value 2. This arises from the fact that, by

(15), the difference δ_n has the probable error $\sqrt{2}\,r$, where r is the probable error of δ_n^{I} and δ_n^{II}. The relative weight of δ_n is therefore ½, whence by (7), $P_d^2 = 2$. The factor P_D^2 remains unchanged. The solution for the correlates is still given by (18), whence,

$$V_n = k_n - k_{n-1}, \qquad v_n = 2\,k_n \tag{21}$$

with check equations as before.

Declinations +45°, +30°, *and* +15°.—For each of these zones

$$d_n = d_n^{I} + d_n^{II} + d_n^{III} + d_n^{IV} \tag{22}$$

where the component differences are of unit weight.

For the alternative procedure just described, $P_D^2 = 1$, $P_d^2 = 4$. The coefficient 3 in the correlate equations (10) is increased to 6 throughout, and the solution becomes

$$\left.\begin{aligned} -560\,k_n &= 99\,\phi_n + 17\,\phi_{n+1} + 3\,\phi_{n+2} + \phi_{n+3} + 3\,\phi_{n+4} + 17\,\phi_{n+5} \\ V_n &= k_n - k_{n-1}, \qquad v_n = 4\,k_n \end{aligned}\right\} \tag{23}$$

where v_n is to be distributed equally among the four component differences δ_n^{I}, δ_n^{II}, etc. The adjusted differences are therefore

$$D_n = \Delta_n + V_n, \qquad d_n^{I} = \delta_n^{I} + k_n, \text{ etc.} \tag{24}$$

with the usual check equations

$$\left.\begin{aligned} &\Sigma V = 0, \quad \Sigma D = \Sigma \Delta \\ &\Sigma v = -\Sigma \phi = -\epsilon, \quad \Sigma d = 0 \end{aligned}\right\} \tag{25}$$

in addition to the closing condition (1), combined with (22).

Declinations 0° *and* −15°.—The relations are shown by Figure 2, in which C and c are adjusted differences corresponding to the observed values Γ and γ. The adjusted differences must satisfy the closing conditions

$$\left.\begin{aligned} \psi_n &= D_n - D_{n+1} + d_n &= 0 \\ \xi_n &= C_n - C_{n+1} - d_n + c_n &= 0 \end{aligned}\right\} \tag{26}$$

which, by summation, furnish the superfluous conditions

$$\Sigma d = 0, \qquad \Sigma c = 0 \tag{27}$$

The differences d_n and c_n are sums of component values for intermediate steps such that for any n

$$\left.\begin{aligned} d &= d^{I} + d^{II} + d^{III} + d^{IV} \\ c &= c^{I} + c^{II} + c^{III} + c^{IV} \end{aligned}\right\} \tag{28}$$

The observed differences, substituted into (26), give the closing errors

$$\left.\begin{aligned} \Delta_n - \Delta_{n+1} + \delta_n &= \phi_n \\ \Gamma_n - \Gamma_{n+1} - \delta_n + \gamma_n &= \theta_n \end{aligned}\right\} \tag{29}$$

The closing errors for the zones, from (27), are

$$\Sigma\,\delta = \epsilon\ (0°), \qquad \Sigma\,\gamma = \eta\ (-15°) \tag{30}$$

Further, from (29),

$$\epsilon = \Sigma\,\phi, \qquad \eta - \epsilon = \Sigma\,\theta \tag{31}$$

To provide for the two additional series of adjustment corrections, W and w, defined by

$$C_{\mathrm{n}} = \Gamma_{\mathrm{n}} + W_{\mathrm{n}}, \qquad c_{\mathrm{n}} = \gamma_{\mathrm{n}} + w_{\mathrm{n}} \tag{32}$$

equations (6) to (9) must be extended. The observation equations, as before, are equal in number. Although each of the differences Δ depends on three comparison photographs, as against two for all the other differences, their weights are not increased because of the relatively great distance through which the telescope must be moved in passing from the equator to the Pole. The weights are therefore

$$p_{\mathrm{D}} = p_{\mathrm{C}} = 1, \quad p_{\mathrm{d}} = p_{\mathrm{c}} = 1/4$$

whence, by an extension of (7),

$$P^2_{\mathrm{D}} = P^2_{\mathrm{C}} = 1, \quad P^2_{\mathrm{d}} = P^2_{\mathrm{c}} = 4 \tag{33}$$

The expressions for the corrections are

$$\left.\begin{aligned} V_{\mathrm{n}} &= \frac{\partial\psi_{\mathrm{n-1}}}{\partial D_{\mathrm{n}}} k_{\mathrm{n-1}} + \frac{\partial\psi_{\mathrm{n}}}{\partial D_{\mathrm{n}}} k_{\mathrm{n}} & \qquad v_{\mathrm{n}} &= 4\left(\frac{\partial\psi_{\mathrm{n}}}{\partial d_{\mathrm{n}}} k_{\mathrm{n}} + \frac{\partial\xi_{\mathrm{n}}}{\partial d_{\mathrm{n}}} j_{\mathrm{n}}\right) \\ W_{\mathrm{n}} &= \frac{\partial\xi_{\mathrm{n-1}}}{\partial C_{\mathrm{n}}} j_{\mathrm{n-1}} + \frac{\partial\xi_{\mathrm{n}}}{\partial C_{\mathrm{n}}} j_{\mathrm{n}} & \qquad c_{\mathrm{n}} &= 4\frac{\partial\xi_{\mathrm{n}}}{\partial c_{\mathrm{n}}} j_{\mathrm{n}} \end{aligned}\right\} \tag{34}$$

in which j_{n} represents the six correlates corresponding to the second series of conditions in (26).

The correlate equations have the form

$$\left.\begin{array}{l} [\alpha\,\alpha]\,k_1 + \cdots\cdots + [\alpha\,\eta]\,k_6 + [\alpha\,\alpha']\,j_1 + \cdots\cdots + [\alpha\,\eta']\,j_6 + \phi_1 = 0 \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\ [\eta\,\alpha]\,k_1 + \cdots\cdots + [\eta\,\eta]\,k_6 + [\eta\,\alpha']\,j_1 + \cdots\cdots + [\eta\,\eta']\,j_6 + \phi_6 = 0 \\ [\alpha'\alpha]\,k_1 + \cdots\cdots + [\alpha'\eta]\,k_6 + [\alpha'\alpha']\,j_1 + \cdots\cdots + [\alpha'\eta']\,j_6 + \theta_1 = 0 \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\ [\eta'\alpha]\,k_1 + \cdots\cdots + [\eta'\eta]\,k_6 + [\eta'\alpha']\,j_1 + \cdots\cdots + [\eta'\eta']\,j_6 + \theta_6 = 0 \end{array}\right\} \tag{35}$$

in which the coefficients are defined by

$$\left.\begin{array}{llll} \alpha_{\mathrm{n}} = \dfrac{\partial\psi_1}{\partial D_{\mathrm{n}}}, & \alpha_{6+\mathrm{n}} = 2\dfrac{\partial\psi_1}{\partial d_{\mathrm{n}}}, & \alpha_{12+\mathrm{n}} = \dfrac{\partial\psi_1}{\partial C_{\mathrm{n}}}, & \alpha_{18+\mathrm{n}} = 2\dfrac{\partial\psi_1}{\partial c_{\mathrm{n}}} \\ \cdots\cdots & \cdots\cdots & \cdots\cdots & \cdots\cdots \\ \alpha'_{\mathrm{n}} = \dfrac{\partial\xi_1}{\partial D_{\mathrm{n}}}, & \alpha'_{6+\mathrm{n}} = 2\dfrac{\partial\xi_1}{\partial d_{\mathrm{n}}}, & \alpha'_{12+\mathrm{n}} = \dfrac{\partial\xi_1}{\partial C_{\mathrm{n}}}, & \alpha'_{18+\mathrm{n}} = 2\dfrac{\partial\xi_1}{\partial c_{\mathrm{n}}} \\ \cdots\cdots & \cdots\cdots & \cdots\cdots & \cdots\cdots \end{array}\right\} \tag{36}$$

These expressions are easily evaluated and arranged in a 24-line table of 12 columns, corresponding to Table VI, which was used for the other cases. The formation of the products $\alpha\alpha$, $\alpha\beta$, etc., and their summation then give the coefficients of the 12 correlate equations (35), and the equations themselves, in generalized form, become

$$\left.\begin{array}{l} 6\,k_{\mathrm{n}} - k_{\mathrm{n+1}} - k_{\mathrm{n+5}} - 4\,j_{\mathrm{n}} + \phi_{\mathrm{n}} = 0 \\ -4\,k_{\mathrm{n}} + 10\,j_{\mathrm{n}} - j_{\mathrm{n+1}} - j_{\mathrm{n+5}} + \theta_{\mathrm{n}} = 0 \end{array}\right\} \tag{37}$$

The solution of these equations is

$$\left.\begin{aligned} -70760\,k_n &= +19239\,\phi_n + 5661\,\phi_{n+1} + 1879\,\phi_{n+2} + 1061\,\phi_{n+3} + 1879\,\phi_{n+4} + 5661\,\phi_{n+5} \\ &\quad + 8338\,\theta_n + 3212\,\theta_{n+1} + 1138\,\theta_{n+2} + 652\,\theta_{n+3} + 1138\,\theta_{n+4} + 3212\,\theta_{n+5} \\ -70760\,j_n &= +8338\,\phi_n + 3212\,\phi_{n+1} + 1138\,\phi_{n+2} + 652\,\phi_{n+3} + 1138\,\phi_{n+4} + 3212\,\phi_{n+5} \\ &\quad + 10901\,\theta_n + 2449\,\theta_{n+1} + 741\,\theta_{n+2} + 409\,\theta_{n+3} + 741\,\theta_{n+4} + 2449\,\theta_{n+5} \end{aligned}\right\} \tag{38}$$

To obtain the adjustment corrections, the correlates k and j are to be substituted into (34), which simplify to

$$\begin{aligned} V_n &= k_n - k_{n-1}, & v_n &= 4\,(k_n - j_n) \\ W_n &= j_n - j_{n-1}, & w_n &= 4\,j_n \end{aligned} \tag{39}$$

The resulting corrections v_n and w_n are to be apportioned equally among the component differences in accordance with (28).

The rather complicated expressions for the correlates are checked by the formulæ

$$-4\,\Sigma\,k = 2\,\Sigma\,\phi + \Sigma\,\theta, \qquad -4\,\Sigma\,j = \Sigma\,\phi + \Sigma\,\theta \tag{40}$$

which are easily derived from the correlate equations (37). Further, the combination of (5), (26), (29), and (32) gives

$$\left.\begin{aligned} \phi_n + V_n - V_{n+1} + v_n &= 0 \\ \theta_n + W_n - W_{n+1} - v_n + w_n &= 0 \end{aligned}\right\} \tag{41}$$

The substitution of (39) into (41) then gives

$$\begin{aligned} k_{n-1} - 6\,k_n + k_{n+1} + 4\,j_n &= \phi_n \\ j_{n-1} - 10\,j_n + j_{n+1} + 4\,k_n &= \theta_n \end{aligned}$$

Since the subscript $n-1$ is equivalent to $6+n-1=n+5$ these formulæ are nothing but the generalized correlate equations (37). Equations (37) and (40) are identically satisfied by (38), which checks not only the coefficients of the correlates but also formulæ (39) for the corrections themselves.

The complete solution is therefore given by (29), (38), (39), and (32). The check formulæ are

$$\left.\begin{aligned} &\Sigma\,V = \Sigma\,W = 0, \quad \Sigma\,v = -\epsilon, \quad \Sigma\,w = -\eta \\ &\Sigma\,D = \Sigma\,\Delta, \quad \Sigma\,C = \Sigma\,\Gamma, \quad \Sigma\,d = \Sigma\,c = 0 \end{aligned}\right\} \tag{42}$$

and, in addition, the closing conditions (26).

b. Numerical Results.—An indication of the internal consistency of the results is given by the summary of reduction for each zone shown in Tables VII and VIII, the first of which relates to the polar comparisons and the inter-connection of the $-15°$ and $0°$ zones, the second to the comparison of adjacent Areas in the same zone. In each case the second column shows the fields compared, in the order used in forming the observed zero-point differences, Δ and δ, which appear in the fourth column. Thus for the Pole and Area 2 (Table VII), $\Delta = +1.74$ is the difference which, applied to the relative magnitudes of Area 2, reduces them to the international zero point as defined by the stars at the Pole. Similarly, for Areas 2 and 3 (Table VIII) the difference $\delta = -1.70$ reduces Area 3 to Area 2. In the last division of Table VII, which relates to the inter-connection of the $-15°$ and $0°$ zones,

*Additional plate, 4537.

the order, for example, 92−116, is such that the tabulated differences reduce the −15° zone to that at the equator.

For most cases the observed differences are the means for two plates as found in section 5c, corrected for atmospheric extinction. The deviations of the individual differences from the mean, expressed in hundredths of a magnitude, are given in the fifth column of Tables VII and VIII. The correction for extinction is always differential, and never large. The derivation of the tables used is described in section 7.

25–26, 2885 129–130, 4434

The remaining columns of Tables VII and VIII relate to the adjustment based upon the closing errors of the various circuits as defined by equations (2) or (26). Thus for the +75° zone

$$\phi_1 = \Delta_1 - \Delta_2 + \delta_1 = +1.74 - 0.04 - 1.70 = \quad 0.00$$

$$\phi_2 = \Delta_2 - \Delta_3 + \delta_2 = +0.04 - 1.50 + 1.52 = +0.06, \text{ etc.}$$

These and the remaining values of ϕ for this zone appear in the second column of Table IX. The closing error for the zone is $\Sigma\phi = -18$, which is checked by the fact that it equals $\Sigma\delta$

TABLE IX

Closing Errors

Circuit	+75°	+60°	+45°	+30°	+15°	0°	−15°
1	0	+11	+24	− 5	+ 5	+ 9	0
2	+ 6	+19	+22	+19	+20	−13	+26
3	0	+ 7	−12	−31	+ 1	− 5	−20
4	0	−16	+ 1	−15	+ 4	− 5	+ 7
5	−13	−14	−31	+ 5	− 7	− 1	+14
6	−11	+ 1	−15	− 2	0	− 1	−23
Zone	−18	+ 8	−11	−29	+23	−16	−12

(Table VIII). Equations (11) and (12) then give the corrections V and v appearing in the sixth column of Tables VII and VIII. These satisfy the conditions $\Sigma V = 0$ and $-\Sigma v = \epsilon = -18$, the closing error of the zone. The adjusted values, D and d, are checked by the closing condition (1), thus

$$+1.69 - 0.01 - 1.68 = 0; \qquad +0.01 - 1.52 + 1.51 = 0, \text{ etc.}$$

In forming the circuits for the other zones, it is to be noted that groups of either two or four differences from Table VIII are to be combined with two adjacent differences from Table VII; and that the initial and final field numbers of the proper group from Table VIII are the same as the Area numbers involved in the polar-comparison differences. Hence for $+45°$, $P-20$ and $P-24$ are to be combined with the group $20-21, \ldots, 23-24$, in Table VIII. To emphasize the grouping, the zone differences in Table VIII do not always begin with the initial Area of the zone. Thus for $+30°$, the sequence of differences begins with $45-46$, the difference for $44-45$ being given at the end of the tabulation for the zone.

The adjustment of the $0°$ and $-15°$ zones requires little comment. The additional condition providing for the closure of the quadrilateral circuit is the second of equations (26), the closing error itself, θ, being given by the second of (29). Thus for the first circuit

$$\begin{array}{lll} \Gamma_1 = -0.15, & \delta_1 = -0.59 & (\Sigma\delta \text{ for Areas 92 to 96}) \\ \Gamma_2 = +0.28, & \gamma_1 = -0.16 & (\Sigma\gamma \text{ for Areas 116 to 120}) \end{array}$$

whence $\theta_1 = 0$, which appears in the last column of Table IX. The values of ϕ, found as already explained, are in the preceding column. The zone closing error for $0°$ is $\Sigma\phi = -16$; but for $-15°$, by (31), it is $\Sigma\phi + \Sigma\theta = -12$, which, by (30), must equal $\Sigma\gamma$, as in fact is the case.

The corrections V, W, v, and w are calculated by (38) and (39), and satisfy the check equations (42). Finally, the adjusted values D, C, d, and c satisfy (26). For example

$$\begin{array}{rr@{\qquad}rr} & D_1\,(P-92) + 1.04 & & C_1\,(92-116) - 0.18 \\ - & D_2\,(P-96) - 0.42 & - & C_2\,(96-120) - 0.27 \\ & d_1\,(92 \text{ to } 96) - 0.62 & - & d_1\,(92 \text{ to } 96) + 0.62 \\ & & & c_1\,(116 \text{ to } 120) - 0.18 \\ \hline \text{Sum} & 0.00 & & -0.01 \end{array}$$

The values of D in Table VII are final zero-point corrections for relative magnitudes. As they stand, results are available only for those Areas which were compared directly with the Pole. Corrections for the other Areas were found by combining adjusted differences in Tables VII and VIII. Thus

$$\begin{aligned} P - 93 &= (P - 92) + (92 - 93) \\ P - 94 &= (P - 93) + (93 - 94), \text{ etc.} \end{aligned} \tag{43}$$

$$\begin{aligned} P - 116 &= (P - 92) + (92 - 116) \\ P - 117 &= (P - 116) + (116 - 117), \text{ etc.} \end{aligned} \tag{44}$$

c. *Precision of Zero Points.*— The principal points bearing on the homogeneity of the results are the residuals for the individual comparison photographs given in the fifth column of Tables VII and VIII, the closing errors in Table IX, and the adjustment corrections

V, v, W, and w in the sixth column of Tables VII and VIII. The residuals but rarely exceed a tenth of a magnitude. The corresponding average probable errors in Δ, Γ, δ, and γ for the different zones are given in Table X. The least satisfactory are the polar comparisons for +60° and +45°. The fluctuations from zone to zone, however, are just what would be expected from the general averages in Table X and the number of values included in each. The average probable error in the mean zero point of a field directly connected with the Pole by 2 plates (3 for 0°) is ±0.040 mag. The corresponding uncertainty for a zone comparison is ±0.036 mag.

TABLE X

Probable Errors of Mean Observed Zero-Point Differences

Dec.	Polar Comp.		Zone Comp.	
	Av. P.E.	No.	Av. P.E.	No.

Means	±0.040	94	±0.036	280

*Inter-zone comparison, 0° and −15°.

TABLE XI

Probable Errors of Closure

Zones	From Closing Errors	From Table X	No. of Steps	No. of Closing Errors
	Triangular Circuits			
+75°	±0.054	±0.056	3	6
60	0.094	0.105	4	6
45, 30, 15, 0	0.097	0.094	6	24
	Quadrilateral Circuits			
0°, −15°	0.129	0.135	10	6
	Zone Circuits			
+45° to −15°	±0.147	±0.188	24	5

In general, these results are consistent with the closing errors shown in Table IX. Regarded as residuals, the closing errors may be used to calculate the probable error of closure. This quantity, however, may be computed directly from the probable errors of the observed differences given in Table X. Table XI summarizes the results. The most reliable comparison is that for the triangular circuits connected with zones +45° to 0°. For the other zones the number of closing errors available is too small to insure a very reliable test; and yet the only discordance is that affecting the zone circuits, for which the result from the closing errors is *less* than would be inferred from the internal agreement of the individual comparisons. The results thus indicate that the precision of the zero-point differences, as indicated in Table X, has not been overestimated.

Of the 170 adjustment corrections, one attains a value of 0.08 mag., and 5 are equal to 0.07 mag. The average, however, is only ±0.024 mag., which, in itself, is evidence that a reasonably satisfactory precision in the zero points has been attained. The matter may be investigated further, however, by calculating the probable errors of the adjusted zero-point differences.[1]

For this purpose we require the probable error r of various linear functions of the adjustment corrections, which, in their most general form, may be expressed by

$$F = \sum_{1}^{6} l_{\mathrm{n}} V_{\mathrm{n}} + \sum_{7}^{12} l_{\mathrm{n}} v_{\mathrm{n}} \tag{45}$$

The reciprocal weight of such a function is

$$\frac{1}{P} = [ll] - \frac{[\alpha l]^2}{[\alpha\alpha]} - \frac{[\beta l \cdot 1]^2}{[\beta\beta \cdot 1]} - \cdots\cdots\cdots - \frac{[\eta l \cdot 5]^2}{[\eta\eta \cdot 5]} \tag{46}$$

in which the symbols are the usual Gaussian notation for well-known functions of coefficients. The expression for the probable error of F is then

$$r = 0.6745 \sqrt{\frac{[\phi k]}{PN}} \tag{47}$$

where ϕ represents the closing errors, k the correlates, and N the number of conditions to be satisfied.

Because of the considerable labor involved, the calculation has been made only for the zones at +75° and at +45°. For the first, all of the fields are connected directly with the Pole, and it is necessary to find the probable error for only a single V, any one of which may be chosen, since the uncertainty affecting them is the same for all. From a numerical standpoint, however, it is simplest to use V_6, and the general function therefore reduces to the single term $F = V_6$.

For the +45° zone, three intermediate Areas occur between each pair connected with the Pole. A reference to Figure 2 shows that the quantities required to reduce the zero points of such a group of Areas to the Pole are

$$D_{\mathrm{n}}, \qquad D_{\mathrm{n}} + d_{\mathrm{n}}^{\mathrm{I}}, \qquad D_{\mathrm{n}} + d_{\mathrm{n}}^{\mathrm{I}} + d_{\mathrm{n}}^{\mathrm{II}}, \cdots\cdots$$

The reduction for the next Area, involving $d_{\mathrm{n}}^{\mathrm{III}}$, is by (1) and (22) equivalent to $D_{\mathrm{n+1}} - d_{\mathrm{n}}^{\mathrm{IV}}$. As far as the calculation of errors is concerned, this case is the same as the second of the above sequence. The functions of the adjacent correction to be considered are therefore

$$F = V_{\mathrm{n}}; \qquad F^{\mathrm{I}} = V_{\mathrm{n}} + v_{\mathrm{n}}^{\mathrm{I}}; \qquad F^{\mathrm{II}} = V_{\mathrm{n}} + v_{\mathrm{n}}^{\mathrm{I}} + v_{\mathrm{n}}^{\mathrm{II}} \tag{48}$$

Here again, the choice of n is arbitrary, although the calculation itself is simplest for n = 6.

---

[1] Helmert, *Ausgleichungsrechnung* (Berlin, 1907), pages 239, 245, 246.

The results found by formulæ (46) and (47) are

$$+75^\circ)\quad r = \pm 0.024 \text{ mag.}$$
$$+45^\circ)\quad r = \pm 0.048,\quad r^{\mathrm{I}} = \pm 0.063,\quad r^{\mathrm{II}} = \pm 0.068 \text{ mag.}$$

where r refers to a field directly connected with the Pole by the step D; r^{I}, to one connected by the two steps $D+d^{\mathrm{I}}$; and r^{II}, by the three steps $D+d^{\mathrm{I}}+d^{\mathrm{II}}$.

As an indication of the increase in precision resulting from the adjustment process, these results may be compared with the corresponding probable errors for unadjusted results. Table X gives, either directly or by obvious combinations of probable errors,

$$+75^\circ)\quad \pm 0.032;\qquad +45^\circ)\quad \pm 0.055,\quad \pm 0.067,\quad \pm 0.077 \text{ mag.}$$

which are to be compared with the above sequence of values.

As already remarked, the +45° zone is one of the least satisfactory. On the average, for the errors affecting the unadjusted results of one, two, and three steps, we may expect

$$\pm 0.040,\quad \pm 0.054,\quad \pm 0.065 \text{ mags.}$$

and for adjusted results, errors about 0.01 mag. smaller.

7. CORRECTION FOR ATMOSPHERIC EXTINCTION

The lack of suitable extinction tables made it necessary in the beginning to follow a somewhat unsatisfactory procedure and base the corrections for photographic extinction on the visual tables of Müller.[1] The old rule of doubling the visual correction was followed, after a rough interpolation for the altitude of Mount Wilson had been made from Müller's results for Potsdam and the Säntis. A summary of these results appears under the heading "Interpolated" in Table XII.

TABLE XII

Later, when Abbot's revised measures of transmission for Mount Wilson[2] became available, the corrections were calculated for both photographic and photovisual magnitudes. Curves of spectral sensitivity were obtained from small-scale spectrograms of skylight, for the plates and the filter used in deriving these magnitudes. Ordinates of the curves were multiplied by the corresponding transmission coefficients and combined to form weighted mean coefficients. The results for the zenith are: photographic transmission, 0.762; photovisual, 0.889; to which correspond the zenith extinctions 0.295 and 0.128 mags., respectively. The corresponding reductions to the zenith, in magnitudes, for different zenith distances are given in Table XII, under the heading "Observed."

---

[1] *Photometrie der Gestirne* (Leipzig, 1897).

[2] *Annals of the Smithsonian Astrophysical Observatory*, 3, 138, 1913.

Although the observed values are to be preferred, the reductions were completed with the interpolated results. As far as the present investigation is concerned, the differences between the two series are negligible.

8. MEASUREMENT OF COORDINATES

a. Long-Exposure Photographs.—These photographs were measured with the Repsold machine described in *Harvard Annals*, 101, p. LI. The microscope *A* through which the observer sees the plate is fixed, and the motion in the two rectangular coordinates is thrown on the plate. This motion is read from two scales, the divisions of which correspond exactly to $1'$ on the plate. By means of ocular scales in the reading microscopes, with divisions corresponding to $0\overset{\prime}{.}1$, the readings can be made by estimation to the nearest $0\overset{\prime}{.}01$. The observing microscope *A* is also provided with an ocular scale in the direction of declination, covering a little more than $5'$, the divisions of which correspond to $10''$. As will be explained presently this scale is used for measuring the y coordinate.

The plate was oriented on the equinox of 1900 by means of the positions of a few stars given in the *Harvard-Groningen Durchmusterung*[1]. The measures were made in zones of constant declination $5'$ wide. An example will best illustrate the way in which the fields were limited. Suppose the field to be measured to be $15'\times 15'$ and the coordinates of the central star to be $x=97\overset{\prime}{.}26$[2], $y=+4'11''$. This star was brought on the ocular scale at the reading $4'11''$, and the x scale (direction of right ascension) was shifted relatively to its mounting until the reading was $97\overset{\prime}{.}26$. The plate was then displaced exactly $5'$ to the south in the y direction and firmly clamped in position. Next, the plate was shifted in the x direction until the reading of the x scale became $7\overset{\prime}{.}50$ less than that of the central star, and observations were begun at the full minute of arc nearest this reading. The button which moves the plate in the x direction was slowly and regularly turned (the y reading remaining unchanged) and each star coming to the transit of the ocular scale of the observing microscope *A* was bisected by the vertical thread. The observer at this microscope then estimated and called out the diameter of the image in seconds of arc and the reading on the ocular scale corresponding to the center of the star. A second observer read the x coordinate, and all the readings were entered in the ledgers by a third person.

The measures were continued until exactly $15'$ in x had been covered. A zone $5'$ wide, with an overlap in declination of about $20''$ on each side, was thus completely observed. The y frame was then unclamped and moved $5'$ to the north and reclamped in position. The second zone was observed like the first, between the same values of x. When all the zones (in the present case three) had been observed in this manner, a second measurement of the plate, quite independent of the first, was begun at once. The duplicate readings were recorded in the ledgers beside those of the first measurement, and, when complete, the observations were immediately compared. Stars of diameter -0 occurring in but one series of measures were only partly remeasured, and no completeness for such stars can be guaranteed. All other objects occurring but once were examined, and, if found to be real stars, were measured again. At the same time, all marked differences between the two measures of the x and y coordinates and of the diameters were looked up and set to rights.

---

[1] *Harvard Annals*, 101, 1918; 102, 1923.

[2] In reality this coordinate is $x = 97\overset{\prime}{.}26 - 100' = -2\overset{\prime}{.}74$.

The fields measured include either three or four zones of 5′ width, according to galactic latitude. In case four zones were measured, the interval in x was extended to 20′. The latitudes and corresponding dimensions are

Galactic latitude	*Field measured*
− 40° to + 40°	15′ × 15′
± 40 to ± 90	20 × 20

For fields 15′×15′ the declination of the center of the region measured is the middle of the zone containing the central star; for fields 20′× 20′ it is the nearer edge of this zone. The limits in right ascension are the exact minutes nearest to the x coordinate of the central star, plus or minus half the side of the measured square. This rule has not been strictly adhered to, but the effect on the limits is small. The exact limits are given for each Area in Table XVIII (page XLIX).

The geometrical centers of the fields are thus always close to the optical centers (the central star), and should be distinguished from the origin for the coordinates x and y, which is always the exact minute of time in right ascension and the multiple of 10′ in declination nearest the position of the central star. The origin of coordinates is given at the head of each section of the *Catalogue*.

With the arrangement of the instrument and the procedure described above, the readings of the x scale and of the ocular scale of the observing microscope A represent approximately the definitive x and, with the difference of some exact multiple of 10′, the definitive y. The reduction consists in finding and applying the small corrections necessary to convert these readings into the final x expressed in minutes of arc, and the final y expressed in minutes and seconds of arc. These corrections were derived by means of the positions of the brighter stars appearing in the *Harvard-Groningen Durchmusterung*. The differences

$$x_{\mathrm{DM}} \textit{ minus } \text{measured } x$$
$$y_{\mathrm{DM}} \textit{ minus } \text{measured } y$$

were formed. If these differences showed no regular change with x, their means were adopted as the zone corrections and applied to all the stars in the zone. If a systematic change with x was revealed, the correction was assumed to be proportional to x and the zone correction was accordingly varied with this coordinate.

The corrected positions of the stars in the overlapping portions of the adjacent zones were then compared. If these showed systematic differences, corrections depending on y were then derived and applied. These never exceed 2″ in y and 0′.02 in x. The correction in x is a consequence of a defective orientation of the transit line of the ocular scale in the observing microscope; that in y, of a defective scale value of the ocular scale. The corrections were applied to the means of the two measurements.

For all Areas except No. 1, the right ascensions were computed by means of the formula

$$\alpha - A = 4\,x \sec \delta,$$

x being expressed in minutes of arc and $\alpha - A$ in seconds of time, where A is the right ascension of the zero point of the rectangular coordinates. The mean declination of the zone in which the star occurs has been used for δ. The maximum error thus introduced amounts to $0^{\mathrm{s}}.5$ for declination +75° and $0^{\mathrm{s}}.1$ for declination +60°; in all other cases it is less than $0^{\mathrm{s}}.1$. The *Catalogue* right ascension is therefore given to the nearest 1^{s} for Areas at declination +75°, and to the nearest $0^{\mathrm{s}}.1$ for the other Areas. The values of $\alpha - A$ were derived from tables giving $\alpha - A$ as a function of x for each zone.

For all Areas except No. 1, the declination of any star is very nearly equal to $D+y$, D being the declination of the origin of coordinates. The differences $\delta-(D+y)$ are shown in Table XIII and may be used to find the declination from the catalogue values of $D+y$. The correction is usually negligible.

TABLE XIII

Values of $\delta-(D+y)$

D	x		
	0′	±10′	±20′
+75°	0″	−3″	−13″
+60	0	−2	− 6
+45	0	−1	− 3
+30	0	−1	− 2
+15	0	0	− 1
0	0	0	0
−15	0	0	+ 1

For Area 1 the right ascension and declination of the stars were computed by means of the formulæ[1]

$$\left.\begin{aligned} \tan(\alpha - A) &= \frac{\sin x}{\cos(D+y)} \\ \tan\delta &= \cos(\alpha - A)\tan(D+y) \end{aligned}\right\} \tag{49}$$

which are of ample precision for the purpose.

b. Diaphragm Photographs.—The rectangular coordinates of all stars observed on the diaphragm plates were required for identification of stars measured at Groningen, or for catalogue purposes in the case of stars not included within the limits of the Groningen fields (the "supplementary" stars of the *Catalogue*). A large Gærtner comparator, provided with motions in two rectangular coordinates, was fitted with adjustable scales, graduated to read minutes, and, by estimation, tenths of a minute of arc directly from the original negatives. The general method of measurement was similar to that used at Groningen, but the precision is only that sufficient for identification of the stars.

---

[1] *Harvard Annals*, 101, p. LXIII.

Since the centers for the rectangular coordinates are the same as in the *Harvard-Groningen Durchmusterung*, the adjustment of the negative on the machine, and of the scales with respect to their mounting, was simplified by the fact that coordinates for the brighter stars were already available. With the plate mounted on the machine and approximately oriented, the central star of the Area was brought to the intersection of the cross-threads. The scales were then shifted relatively to their mounting until the readings equalled the coordinates of the central star as given in the *Durchmusterung*. After adjustment for orientation by means of stars near the edge of the field, the scales were clamped in position and the readings on the central star finally checked. With this arrangement, the x and y coordinates of any star could be read directly from the scales with all necessary precision and without any reduction whatever. As a matter of fact, the y scale was so graduated that the quantity read was the minutes and tenths of the approximate declination, which differs from y by some multiple of $10'$. In order that this simple procedure might also be followed for fields south of the equator, it was necessary only to turn the y scale end for end before beginning the measures.

The stars visible in the observing microscope were identified by means of the configurations shown on the numbered charts described in section 5b, page XX. The various divisions of the chart were measured successively in a systematic manner, the results being entered on cards, which were afterwards arranged in the order of increasing x coordinate for combination with the Groningen measures, or for segregation into the list of supplementary stars.

The right ascension was obtained by multiplying the x coordinate by a reduction factor and applying the result to the right ascension of the adopted origin, which is always the exact minute nearest the position of the central star. This transformation was made only for the supplementary stars, observed at Mount Wilson but not at Groningen. For all the other stars the coordinates measured at Groningen were adopted for the *Catalogue*. For these it was only a question of identification with Groningen measures, for which the right ascension itself was not required. As in the case of the long-exposure photographs, Area 1 is an exception, and had to be treated by means of equations (49).

Since the scale of the photographs is approximately $1' = 2.2$ mm, the graduation of the special scales presented no difficulty. For the fields used the ordinary plate corrections are small, and the error in the coordinates is sensibly that affecting the estimated tenths of a minute of arc. The error in orientation and in setting the scales for the coordinates of the central star is added to that of the estimates; but both orientation and adjustment of scales were always carefully checked. Moreover, the adopted coordinates for the supplementary stars depend on duplicate measures by two observers, made with independent adjustments. In general, therefore, these coordinates should be correct to the nearest $0'.1$.

9. COMBINATION OF GRONINGEN AND MOUNT WILSON MEASURES

The diameters of images measured at Groningen on the long-exposure photographs were reduced to the magnitude scale of the diaphragm plates in the manner described in section 5a. The results were transferred to sheets, which were arranged in catalogue form and provided with additional columns to facilitate combination with the diaphragm magnitudes. These sheets were then forwarded to Pasadena for the final stage of the reduction. Comparison with the numerous diaphragm magnitudes showed that in several instances the scale determined with the aid of the sequences of selected standard stars that had been sent to Groningen could be slightly improved. This illustrates one of the circumstances referred to in section 5b which led to the extensive observation of magnitudes at Mount Wilson. When the probable error of a single magnitude is relatively large, the standards must be numerous, if satisfactory results are to be obtained, especially when the scale is to be extended beyond the limiting magnitude of the standards. Any systematic correction indicated by comparison with the more abundant data available at Mount Wilson was applied to the Groningen magnitudes. The results were then combined with the diaphragm magnitudes.

For Areas 1–25 the weighting was in accordance with the probable errors given in section 10; for the remaining Areas, however, it was decided after some further consideration of the various sources of error to give individual magnitudes from diaphragm and long-exposure photographs the same weight. In the majority of cases, however, the effect on the adopted mean magnitude arising from this difference in weighting is inappreciable.

10. PRECISION OF THE MAGNITUDES

The probable error of a final catalogue magnitude depends on the uncertainty in zero points and in the adopted mean scale of magnitudes, and on accidental errors of measurement. The zero-point errors have been considered in section 6c. The error affecting the adopted mean scales is difficult to estimate, but, except for very faint stars, is probably small, since the differences in the scales established with the aid of different apertures (differential scale errors) are in general small.

The combined effect of differential scale error and accidental errors of measurement and reduction is easily determined by means of the deviations of individual magnitudes from the adopted mean values. Because of differences in plates and in the measurement and reduction, it is desirable to discuss the results from diaphragm and long-exposure photographs separately.

Diaphragm Photographs.—Average residuals were formed for about 25 stars in each of 15 Areas, the selection being at random, except that 15 of the stars in each field were so faint that only two values were available—those derived from the 15-minute exposures with the full aperture, one depending on the scale determination with the $60-32$ combination, the other on the determination with the $60-S$ combination. The remaining 10 stars in each Area average about two magnitudes brighter, but in general are fainter than the fourteenth magnitude. Their mean magnitudes are based on an average of eight separate values and represent four or five different determinations of the scale. The results are

No. Values	*Av. Res.*	*P. E.*	*No. Stars*	*Mag. Interval*
2	±0.093	±0.111	225	16–18
8	±0.121	±0.109	144	14–16

The probable error is that of a single magnitude, calculated by the formula

$$\text{P. E.} = \pm 0.845 \frac{[v]}{\sqrt{n(n-1)}} = \pm 0.845 \frac{[v]}{n} \sqrt{\frac{n}{n-1}}$$

where n is the number of values from which the magnitude has been found and the factor $[v]/n$ is the average residual. These results show no dependence of precision on brightness. A more careful segregation of residuals according to magnitude, supplemented by data for very faint stars from about 30 additional Areas, reveals, however, a rapid increase in the residuals for the last magnitude above the limit of the plate, which averages 18.5. At this point the average residual referred to mean magnitudes based on two values is ±0.13 mag. The increase from ±0.093 given in the above tabulation is caused by a systematic difference in the scales established with the screen and the 32-inch diaphragm (see section 11), which appreciably affects the agreement of magnitudes for the faintest stars. A probable error computed under these circumstances has little significance and is omitted.

Table XIV

Probable Errors for Bright Stars

Mag.	Av. Res.	Av. No. Values	P. E.	No. Stars
<8	±0.140	5.1	±0.131	7
8–9	0.141	7.1	0.128	14
9–10	0.154	9.2	0.138	16
10–11	0.154	10.3	0.137	17
11–12	0.140	13.6	0.123	19
12–13	±0.147	14.9	±0.128	27

Some increase in error is also to be expected for bright stars. To test this, average residuals were formed for 100 stars brighter than the thirteenth magnitude distributed throughout 92 different Areas. The results, grouped according to brightness, are given in Table XIV. Since the number of stars is here but little greater than the number of fields, the effect of differential scale error is accidental in character. The probable error is about a fifth greater than that for stars in the magnitude interval 14 to 17.

Long-Exposure Photographs.—The errors affecting results from these plates may be determined either by comparing magnitudes for the same star obtained from the primary and secondary exposures, or by comparing the mean from the two exposures with the mean for the same star derived from the diaphragm plates. Both methods have been used.

Table XV

Probable Errors from Comparison of Primary and Secondary Images

Mag.	Av. Diff.	P. E.	No. Stars
13.8	±0.291	±0.174	27
14.7	0.297	0.177	57
15.4	0.249	0.149	122
16.3	±0.233	±0.139	114

The average differences between magnitudes from primary and secondary images for 320 stars in 15 different Areas, arranged according to brightness, give the results shown in Table XV, with a weighted mean probable error of ±0.153. Here the probable error for the result from a single image is 0.845 × 0.707 or 0.597 times the average difference. Further, 1142 stars in 20 different Areas, similarly treated, give an average probable error of ±0.164.

The comparison with magnitudes from the diaphragm plates is based on 1107 stars in different Areas. The mean difference without regard to sign is ±0.176 mag., which corresponds, closely enough, to a probable difference of ±0.149. The mean values from the diaphragm and long-exposure photographs include, on the average, 5.08 and 1.28 individual magnitudes, respectively. Since the two means are independent, the required probable error for a single magnitude from a long-exposure photograph is determined by

$$(0.149)^2 = \frac{(0.110)^2}{5.08} + \frac{r^2}{1.28}$$

whence $r = \pm 0.159$. The use of ±0.13 for the probable error of a diaphragm magnitude would reduce this result by only 0.003.

The agreement between these various results is as close as can be expected in view of the differences in the data and the approximate method used to calculate the probable errors. The errors of both series of measures show some dependence on brightness, but in the region of well-determined results ±0.11 mag. may be adopted as the probable error of a single diaphragm magnitude and ±0.15 mag. as the corresponding error for the long-exposure photographs. The relatively large value for the latter series is accounted for by the coarse grain of the plates and the fact that an individual magnitude depends on a single image, whereas each diaphragm magnitude is based on two images measured on a plate of finer grain.

The probable error of a catalogue magnitude varies within rather wide limits and depends on a number of factors—the total number of observations, the relative number from diaphragm and long-exposure photographs, the brightness of the stars, and the number of steps involved in the determination of the zero point. Although an estimate of the uncertainty in individual cases can be made with the aid of the foregoing results, general indications covering all possible conditions are difficult to formulate. As an illustration, however, we may consider stars of the fifteenth magnitude or fainter, in an Area involving a two-step zero point. From the results in section 6c the probable error of the zero point is estimated to be ±0.045 mag. For individual diaphragm and long-exposure magnitudes, we adopt ±0.11 and ±0.15 mag., respectively, as above. Further, it is supposed that each mean magnitude includes one value from a long-exposure photograph. For different numbers of observations the probable error of the mean should then run somewhat as follows:

No. Obsns.	1	3	5	7	9	11	13	15
P. E. Mean	±0.157	0.086	0.070	0.063	0.059	0.057	0.055	0.054 mag.

For fields connected directly with the Pole, the errors should be a little smaller; for those involving three steps in the zero point, a little larger.

These results show that little precision would have been gained for the faint stars by pushing the zero-point determinations to a higher degree of accuracy. On the other hand, the accuracy of the zero points is not such as to utilize fully the precision of the relative magnitudes of stars for which the number of observations is large. Should occasion demand, however, the zero points can be improved with the expenditure of comparatively little labor, whereas the improvement of the relative magnitudes would be a much more serious undertaking.

11. INTERNAL AGREEMENT OF SCALES

The accordance of the photographic magnitude scales derived with the aid of wire-gauze screens and diaphragms of different size was investigated some years ago in connection with measures of stars near the Pole.[1] The abundant material used for the present *Catalogue* permits a similar test.

The comparison was restricted to 27 Areas, selected at random, except that rich fields were chosen in order that a representative number of brighter stars might be available. Residuals referred to the means of the diaphragm magnitudes were collected from the reduction sheets of each Area for each of the following combinations of apertures:

15-minute exposures $60-S$, $60-32$
2-minute exposures $60-32$, $60-14$

A maximum of 10 stars per magnitude was used for each combination in each Area. The number of bright stars, however, is usually less than this limit; the selection from the much more numerous faint stars was random, although an attempt was made to obtain a representative distribution over the field. The resulting systematic deviations are given in Table XVI, where the algebraic signs are such that when the tabulated differences are applied to the scale established by the combination of apertures shown in the column headings the result is the adopted mean scale.

Table XVI
Differential Scale Errors

Mag.	$60-14$ (2^{m})		$60-32$ (2^{m})		$60-32$ (15^{m})		$60-S$ (15^{m})	
	Dev.	No.	Dev.	No.	Dev.	No.	Dev.	No.
9.5	+0.02	45	−0.09	38	......	...	......	...
10.5	+ .03	81	− .07	82	−0.11	12	+0.20	17
11.5	+ .03	220	− .02	212	− .01	87	+ .18	71
12.5	.00	360	− .03	359	+ .03	168	+ .14	157
13.5	− .03	499	− .06	500	+ .07	242	+ .13	230
14.5	− .02	538	− .07	538	+ .02	269	+ .14	268
15.5	+ .01	540	− .03	540	− .01	270	+ .06	270
16.5	− .02	519	+ .01	509	.00	270	+ .03	270
17.5	−0.03	181	+0.03	179	+ .05	269	− .06	269
>18	......	...	......	...	+0.10	182	−0.11	182

As differential scale errors, these results are satisfactory except for the $60-S$ combination. Here it is disappointing to find that the small systematic divergence of 2 per cent revealed by the original test has increased to 4 or 5 per cent. No certain explanation of this anomaly has been found. Any change in the screen constant must have occurred between the two investigations, because both tests include measures well distributed over the respective periods of observation, and a subdivision of the Selected Areas into smaller groups and an extension of the test to other Areas show that the divergence is much the same for all the groups examined.

When first discovered it was feared that the effect on the mean magnitudes might be serious, but that seems not to be the case. Except for the faintest stars, the magnitudes derived with the various diaphragms, all of which give reasonably accordant results, are of dominating influence in determining the mean scale. The extent to which this is the case does not appear from the data in Table XVI, for, through the omission of the residuals for the 9-inch diaphragm and the combination of certain others, the numbers of values given in the table do not indicate the true relative numbers of magnitudes obtained by the different combinations of apertures. To magnitude 17.5 or 18.0 the adopted scale is therefore essentially that of the diaphragms, and it is only between 18.0 and the limit at 18.5 or fainter that much disturbance is to be feared. Nor is it likely that the extension of the scale to the limiting magnitude of the *Catalogue* by means of long-exposure plates has been seriously affected. Any such extension is determined largely by considerations of continuity and regularity over the entire range of brightness, and a sudden change in scale near the point at which the extension begins receives but little weight.

---

[1] Seares, *Mt. Wilson Contr.*, No. 97, Table XI; *Astrophysical Journal*, 41, 231, 1915.

In so far as it affects stars brighter than mag. 16.5, the foregoing conclusion finds a direct test in the following section.

12. COMPARISON WITH THE INTERNATIONAL PHOTOGRAPHIC SCALE

As already explained, the scale of magnitudes has been established independently in each Selected Area, the polar comparisons being used only to determine the zero point. Since the methods applied in determining scales for the Areas are essentially the same as those used for the scale of the North Polar Standards,[1] accordance with the Standards is to be inferred. A direct comparison is desirable, however, since a satisfactory agreement with the scale of the Standards means accordance with the international photographic scale.[2]

For Areas compared directly with the Pole and to the limiting magnitude corresponding to exposures of 2 minutes, the polar-comparison photographs may be used for such a test. In forming the mean zero-point correction, differences of the form

$$PS - RM = z$$

were calculated for individual stars covering the interval of brightness represented on the comparison photographs. In this formula PS represents the magnitude of a star in an Area as read from the curve of magnitudes defined by the North Polar Standards. RM is the relative magnitude of the same star, and z the zero-point correction as determined from this star. The adopted zero-point correction is Z, the mean of the several values of z. Further, the adopted mean magnitude of the star is

$$m = RM + Z = RM + z - v$$

where v is the deviation of z from the adopted mean zero-point correction. Hence

$$PS - m = v.$$

The magnitude PS is referred to the scale of the Polar Standards, while m is referred to the scale derived for the Area in question. Any scale difference thus enters directly into v, along with the accidental errors. The scale comparison therefore requires only the collection and combination of the residuals in the zero-point differences in such numbers as to eliminate, or at least to minimize, the accidental errors.

---

[1] *Mt. Wilson Contr.*, No. 98; *Astrophysical Journal*, 41, 259, 1915.
[2] *Transactions of the International Astronomical Union*, 1, 1922.

Table XVII shows the mean of these residuals, arranged according to magnitude, for four groups of 9 or 10 Areas each, and for the entire 37 Areas for which polar comparisons were made.

TABLE XVII

Comparison of Catalogue Scale with Scale of Polar Standards

Mag.	Group 1		Group 2		Group 3		Group 4		Total, 37 Areas	
	Dev.	No.	Dev.	No.	Dev.	No.	Dev.	No.	Dev.	No.
11.5	+0.01	34	+0.01	12	−0.09	6	+0.03	6	0.00	58
12.5	− .02	46	− .03	38	+ .06	44	− .05	53	− .01	181
13.5	− .01	67	+ .05	96	+ .02	108	− .03	127	.00	398
14.5	− .01	122	− .02	110	+ .01	128	.00	168	.00	528
15.5	+ .03	76	−0.02	95	− .04	101	+0.04	128	.00	400
>16	−0.01	46	......	...	−0.01	6	......	...	−0.01	52

Besides ordinary accidental errors of measurement and a possible systematic difference in scales, the deviations are also affected by differences in gradation in the various exposures on the polar-comparison photographs. Although these enter accidentally into results from different plates, both the third and fourth groups show small progressive changes in the deviations which probably arise from this source. These disappear in the final mean, and as a whole, there is almost perfect agreement between the scale of the *Catalogue* and that of the Standards. Since the Polar Standards are in sensible agreement with the international scale,[1] this demonstrates the general accordance of the scale of the *Catalogue* with the international scale for the magnitude interval 11.0−16.5. Below this, to magnitude 17.5 or 18.0, agreement is also to be expected, although data for a direct test are not available.

13. THE CATALOGUE

The *Catalogue* gives magnitudes for stars in the 139 Areas on and north of the declination parallel at −15°. The positions of the individual Areas may be found by consulting the different sections of the *Catalogue;* they may also be found, collected in tabular form, on pages XLVIII and VI, respectively, of *Harvard Annals*, **101** and **102**. These tables give both equatorial and galactic coordinates of the centers for rectangular coordinates, and the equatorial and rectangular coordinates of the central star for each Area.

The *Catalogue* is arranged in the serial order of the Areas. The results for each Area are divided between a main list, which gives mean magnitudes of all stars within the limits of the field adopted at Groningen, and a supplementary list, which includes stars outside the Groningen field and hence measured only at Mount Wilson. To simplify the paging of the *Catalogue*, the supplementary stars for a few Areas have not been given a separate title line. They may be distinguished, however, by their numbers.

---

[1] The Polar Standards of *Mt. Wilson Contr.*, No. 97; *Astrophysical Journal*, 41, 206, 1915, strengthened by additional material (*Mt. Wilson Contr.*, Nos. 234, 235; *Astrophysical Journal*, 56, 84, 97, 1922), which reduces the accidental error of individual magnitudes without appreciably changing the scale, represent the contribution from the Mount Wilson Observatory to the magnitude scale adopted at the Rome meeting of the International Astronomical Union. For residuals referred to the adopted scale, see *Transactions of the International Astronomical Union*, 1, 71, 1922.

This division arises from the fact that the Groningen and Mount Wilson fields do not coincide in center, size, or shape. The former are 15′×15′ (gal. lat. <40°) or 20′×20′ (lat. >40°), as indicated in the Area heading, and are centered as described on page XXXVII. The Mount Wilson fields are always circular, 23′ in diameter, and centered on the central star. Since homogeneous data within an accurately-known field are essential for statistical purposes, the stars observed only at Mount Wilson, which in general do not attain the limiting magnitude reached at Groningen, are relegated to the supplementary lists; had they been included with those measured on the long-exposure plates, the results would not have been uniform in limiting magnitude. As a matter of fact, the *Catalogue* as a whole is not uniform in this particular; the limit varies from field to field, but for any given Area the results in the main list are homogeneous, except in so far as the limiting magnitude may be affected by distance from the optical center of the field. This influence, however, can be determined and allowed for.

Counts of stars in both Groningen and Mount Wilson fields were made before the two series of measures were combined and have been published elsewhere;[1] but statistical applications of the present *Catalogue* in which size of field or limiting magnitude is of importance must be restricted to the main lists of stars.

Numbering of Stars.—To save space the catalogue numbers are indicated by column headings in the manner familiar in the various *Durchmusterung* catalogues. Stars of the supplementary list are distinguished by an appended "*s*". The total number of stars in the main and supplementary lists is 44,926 and 23,015, respectively, or 67,941 in all.

Magnitudes.—Within the limits of precision indicated in sections 6c, 10, 11, and 12, the magnitudes are on the international photographic scale.

Comparison of results from the 60- and 15-minute exposures revealed a considerable number of objects which, although brighter than the limiting magnitude, do not appear on the short-exposure photographs. For most of these the long-exposure image gives no suggestion of a defect in the film. Re-examination of the short-exposure plates showed, however, that only in rare instances had a star really been overlooked during measurement. The questionable objects must therefore be either variables or—notwithstanding the normal appearance of the images—defects. With one possible exception, however, no single instance of assured variability has presented itself in the entire investigation. Variables may have been observed, their changes in brightness, which must have been moderate, lying concealed in the errors of observation; but the percentage of such cases is probably too small to account for the number of discordances between the two series of measures.

There can be little doubt that most of these objects are spurious; some of them are certainly so, because they are bright and yet fail to show secondary images on the long-exposure plate, as they should if real stars. But since some of the fainter ones, which lack this control, may be variables, it is impossible to reject them outright. The magnitudes in question have accordingly been distinguished by an appended "d," signifying a probable defect. The number of instances of this kind is such as to suggest an increase in the caution normally to be exercised in accepting magnitudes based on single images.

---

[1] *Mt. Wilson Contr.*, No. 301; *Astrophysical Journal*, 62, 320, 1925.

The symbols immediately following the magnitudes have the following significance:

? Existence of star doubtful. The object is either outside the limits of the field measured at Mount Wilson on the photographs of 15 minutes exposure, or too faint to be visible on these photographs. In addition, the image on the long-exposure plate presents some peculiarity which suggests the possibility of a defect in the film.

d Object invisible on short-exposure photographs although, as measured at Groningen, it appears to be brighter than the limiting magnitude of these photographs. Long-exposure image apparently normal. The object is probably a defect, but it may be a variable.

: A double star, the catalogue magnitude representing the combined light of the components. Differences in relative brightness, in separation, and in exposure time prevent a uniform treatment of doubles. The notes at the end of the *Catalogue* should in general be consulted for further details.

x Image diffuse. This notation refers to the image on the long-exposure plates. If otherwise unobserved, the object is possibly a small nebula.

n A nebula.

† This symbol occurs only in the case of double stars and indicates that two magnitudes only are available for one of the components and that these differ by more than 0.8 mag.

w Measured only at Mount Wilson.

h Magnitude from *Harvard Annals*, 101 or 102, corrected by an approximate reduction to the international scale.

* See notes at end of *Catalogue.*

Magnitude in Bold-Face Type.—The central star of the Area. Harvard visual magnitudes of these stars may be found in *Harvard Annals*, 101, 102, pages XLVIII and VI, respectively.

Number of Observations.—The figures following the adopted magnitude in the first column indicate the number of individual values on which the *Catalogue* mean is based. A few stars within the Groningen fields could not be measured on the long-exposure plates because of defective images or confusion with the secondary image of another star. With these exceptions, the magnitudes of the main list always include at least one value from the plates of 60 minutes exposure and single values are always from this source. Magnitudes from the secondary images on these plates are available only for stars brighter than about the sixteenth magnitude. All observations in excess of two, and in most instances those in excess of one, are therefore from the diaphragm plates of 2 minutes and 15 minutes exposure.

The magnitudes for all supplementary stars are from the diaphragm plates, and no star has been retained for this list unless at least two individual values from different plates are available.

Individual magnitudes from long-exposure plates are based on one image; those from diaphragm plates, on two images of equal exposure on the same plate.

Equinox.—The right ascension and declination are for 1900. Approximate positions for other epochs may be found with the aid of the precession for 25 years given at the bottom of each page of the *Catalogue.*

Right Ascension and x Coordinate.—The right ascension is given to the nearest tenth of a second for stars in the main list, except for Areas 1–8, and to the nearest second for the supplementary stars. Except for Area 1, α was calculated by the formula

$$\alpha = A + 4x \sec \delta$$

where A is the right ascension of the origin of coordinates given at the head of each Area and x the tabulated rectangular coordinate, expressed in minutes of arc. Values of x greater than 50 are to be subtracted from 100 and given the negative sign. All other values of x are positive and are to be used as they stand.

The hour of right ascension is on the left at the top of the page, the minutes in the heading of the right ascension column. In case the printed number of seconds is greater than 60 or any multiple of 60, that multiple is to be dropped and the entry at the head of the column increased by the corresponding number of minutes. The exact limits of x for the Groningen fields are given in Table XVIII.

Table XVIII

Limiting Values of x Coordinates

Area	Limits	Area	Limits	Area	Limits	Area	Limits

35	95 − 15	70	94.53 − 14.53	105	85 − 5	...	....

Declination and y Coordinate.—The degrees of declination appear on the right at the top of the page. The body of the table gives the values of $y + n \times 10'$, where $n \times 10'$ equals the minutes of D, the declination of the origin of coordinates shown in the Area heading. The tabulated quantity is therefore the minutes and seconds (minutes and tenths, in the case of supplementary stars) of $y + D$, which, in general, differs from the declination of the star for 1900 by a negligible amount. (See Table XIII.) Area 1 is an exception, for which the relations between x and y and α and δ are defined by equations (49). Numerical examples illustrating the use of these formulæ may be found in *Harvard Annals*, **101**, page LXXXVI.

Acknowledgments for assistance are due to many. First to Messrs. Babcock, Fath, and Shapley for their share in the execution of the observational program, and to Mr. W. P. Hoge, who served as night assistant during most of the time that the observations were in progress.

Further, to Mr. T. W. de Vries, observer at the Groningen Laboratory, who made all the measurements of the long-exposure plates, and to the computers of the Laboratory, E. J. Rondeel and J. M. de Zoute, who performed the greater part of the reductions.

And finally, to the members of the Computing Division who made the measures and routine reductions at Mount Wilson. Miss Carolyn Burns, Miss Helen Burns, Miss High, Miss McClees, Miss Smith, Miss West, Miss Winn, and Miss Wolfe all had some part in the work; but by far the greater portion has fallen to Miss Joyner and Miss Richmond, who are responsible, not only for the measurement and reduction of many individual plates, but also for the determination of the coordinates of the stars and the combination of the results, in catalogue form, with those obtained at Groningen from the long-exposure photographs. The completeness and consistency of the *Catalogue* in respect to the innumerable details which arise in the compilation of any extensive series of data are due to the unremitting care of Miss Joyner.

Any expression of obligations would be incomplete without some reference to the stimulating interest of Kapteyn in the attempt to increase our knowledge of the number and brightness of the stars, an undertaking which to our deep regret he was unable to see completed. The initiative for this investigation was his, as it was for so many others. Under the impetus of his discovery of stream motions among the stars, sidereal astronomy entered upon a period of activity which tacitly recognized the galactic system as a unit, presenting a high degree of organization and many regularities of structure. In the systematic determination of magnitudes on a large scale Kapteyn quickly saw one of the essentials for any detailed knowledge of the structural features of the system, and to the practical aspects of this question he gave much time and thought. The present volume is a contribution to the data upon which a more intimate knowledge of the galaxy must ultimately be based.

F. H. S.

NOTES TO THE CATALOGUE

Nearly all of the stars requiring special mention are doubles which have been measured differently at Groningen and at Mount Wilson. On that account the necessary comment can be expressed in tabular form. Thus the first entry in the table below relates to a double star in Area 18 whose catalogue coordinates are $x = 4'.48$, $y = 2'\,31''$. The catalogue magnitude is the combined brightness of the components as determined at Groningen. At Mount Wilson both components were measured, the resulting magnitudes being those shown in the third column of the table.

The second entry represents the alternative case, in which the components were measured separately at Groningen and appear in the *Catalogue* as separate stars, whereas at Mount Wilson they were measured as a single star having the magnitude given in the third column.

Objects requiring special comment are distinguished by numbers enclosed in parentheses in the third column. These refer to remarks at the end of the table.

	3.1	7 48	(5)	

(1) Nebula. Measured at Mount Wilson only.

(2) Measured at Groningen and marked x. Object visible on Mount Wilson plates but too diffuse to measure. Probably nebula.

(3) Nebula. N. G. C. 3254.

(4) Measured at Mount Wilson only. Image diffuse, perhaps nebula.

(5) Measured at Mount Wilson only. Probably variable. Appears brighter than the star $x = 3'.30$, $y = 6'\ 37''$ by about 0.2 mag. on Mount Wilson plates but on Groningen plate appears 0.6 mag. fainter.

(6) Measured at Mount Wilson only.
